---

hello-app

- ✓ *String interpolation.*
- ✓ *Creation of components.*
- ✓ *Structure of an angular project*

---

1. **Create the hello-app (just like in the previous exercise).**

2. **Serve the application and open it.**

3. **Modify the app.component.html file.**

   Eliminate everything after the <div> and add a <p> with a welcome text message.

   Save the file and see the result in the browser.

4. **Verify the string interpolation and hot module replacement.**

   Go to the app folder.

   Open the `app.component.ts` file.

   Change the value of the string title.

   ```
   title = 'hello-app';
   ```

   Use `{{ title }}` in the html file to show the title string value.

   Save the file and check what happens in the browser.

5. **Create a new component.**

   Add a new terminal to your VS Code.

   CLI

   > **cd** hello-app

   > **ng** generate component new

   Verify that the component is registered on the app.module.ts file.

   Verify and feel free to modify the new.component.html file.

6. **Identify the selector from the new.component.ts file.**

   ```
   selector: 'app-new'
   ```

7. **Import the component in the app.componet.ts file.**

   ```
   import { NewComponent } from './new/new.component';
   ```

8. **Use the selector in the app.component.html file.**

   ```
   <app-new></app-new>
   ```
